

## *Mac OS X: I upgraded to OSX 10.5.7 with java 1.5.0\_19, how can I have CGoban back ?*

There seem to be some trouble with the java 1.5.0\_19 Apple version. We recommend you to uninstall CGoban then to reinstall it again. Here is the method:

- Go to /Applications/Utilities/Java Preferences
- Choose the 'Network' tab
- Then 'View Cache Files' button (this will list the java web start applications)
- Click on CGoban
- Click on the cross to erase it

Then reinstall by clicking the "cgoban3 with java web start" link on the [KGS download page](#). This should fix the issue.

If it doesn't not install the client but run textedit. Then download the "cgoban3 with java web start" jnlp page on your computer. Then right click on it and select "get informations" then "open with" and choose "java web start".

If "java web start" is not suggested, select "Other" then travel through your disk from System, Library, CoreServices and select "Java Web Start". The file association should then work in the right way.
